

Which treatment issues does each article describe?

BioDEX links medical articles to named categories. One article can match several categories.

INPUT A: 8 medical articles

Unstructured case-report text

bio-33e9404292ee

“Despite the initial improvement in symptoms, she gradually worsened.”

“The treatment with gentamicin and ceftriaxone was ineffective, . . .”

Two excerpts from Garcia et al.; the model received the full frozen report.

INPUT B: 8 category names

A structured list of possible labels

Drug ineffective

Off label use

Product use in unapproved indication

Nausea

Condition aggravated

Acute kidney injury

Diarrhoea

Thrombocytopenia

Pair every article with every category: $8 \times 8 = 64$ candidate pairs

Ask GPT-6 Luna about each article–category pair

“The medical report {report} describes {reaction} as an adverse drug reaction or drug-treatment issue affecting a reported patient.”

Prompt excerpt. The full fixed prompt also excludes background-only mentions.

True: retain 10 pairs

The model says the relation holds.

False: omit 54 pairs

The model says the relation does not hold.

OUTPUT: structured article–category rows

Two of the 10 retained pairs, both from the article above

Article ID	Category
1 bio-33e9404292ee	Condition aggravated
2 bio-33e9404292ee	Drug ineffective

COMPARE AFTERWARD

Published annotation for each displayed pair

- 1 **Present:** agreement
- 2 **Absent:** disagreement

Published labels are kept separate from model inputs.

Across all 64 pairs: 11 annotations are positive. Of 10 retained pairs, 4 have that annotation. An absent annotation is a dataset-negative label; it does not establish clinical absence.
